Abstract

A systematic investigation into the reactions of *o*- and *p*-phenylenediacetic acid with zinc(II) and cadmium(II) salts in the presence of the semi-rigid 1,4-bis(2-methylimidazol-1-ylmethyl)benzene (pbmeix) co-ligand is reported. Five new coordination polymers – [Zn(μ-opda)(μ-pbmeix)_{0.5}]_n **1**, {[Zn(μ-ppda)(μ-pbmeix)]·H₂O}_n **2**, {[Zn(μ-ppda)(μ-pbmeix)]·0.5pbmeix·H₂O}_n **3**, {[Cd(μ-opda)(μ-pbmeix)]·0.5DMF}_n **4** and [Cd(μ-ppda)(μ-pbmeix)_{0.5}]_n **5** (o/ppda = 1,2-/1,4-phenylenediacetate) – have been prepared and structurally characterised. Complexes **1** and **5** were found to form three-dimensional coordination networks, **2** forms a two-dimensional structure whereas both **3** and **4** form one-dimensional structures. **1** and **4** are opda complexes in which the dicarboxylate shows a tridentate coordination mode in **1** and a tetradentate coordination mode in **4**. Complexes **2**, **3** and **5** are ppda complexes in which the dicarboxylate adopts bidentate (**2**, **3**) and hexadentate (**5**) coordination modes. The structure of **2** contains interpenetrated 2D frameworks and is a polycatenane with ppda linkers from one framework passing through Zn₂(μ-pbmeix)₂ rings from a neighbouring framework. Compounds

3 and **4** form one-dimensional coordination polymer nanotubes. The thermal stability of complexes **1-4** and luminescence properties of complexes **1** and **4** are also reported.

Keywords: Coordination polymer, Phenylenediacetate complexes, 1,4-bis(2-methylimidazol-1-ylmethyl)benzene complexes, Zinc(II) complexes, Cadmium(II) complexes.

Introduction

Coordination polymers (CPs) are compounds that are formed by linking together inorganic metal nodes with organic linkers into polymeric structures that extend in one, two, or three dimensions [1, 2]. The synthesis and structural characterisation of CPs has attracted considerable interest over recent years due to the diversity of the structures and their potential uses in applications such as adsorption, gas storage, separation and catalysis, especially when porous [3-5]. The structures of CPs are dictated by the nature of both the metal centres and the organic ligands, with the reaction conditions also playing an important role: the solvent, temperature and pH influence the product in many cases [6-8]. The organic linkers, in particular, play a crucial role in determining the nature of the CP, with the number and orientation of the donor groups, ligand length and rigidity all important factors in the topology, porosity and degree of interpenetration observed [9, 10].

The most commonly used organic ligands are polycarboxylates, polyphosphonates, polysulfonates and N-containing heterocycles [11]. Although most ligands employed to construct CPs are rigid, there has been increasing interest in employing semi-rigid ligands, as these allow for more variable coordination modes while the absence of complete flexibility provides for relatively robust and stable frameworks while maintaining the potential for porosity [12-14]. The semi-rigid 1,2-, 1,3- and 1,4-phenylenediacetate ligands have been exploited under different reaction conditions to prepare CPs with diverse structural features [5, 7, 15-18]. The

presence of the flexible -CH₂- spacers together with the rigid central aromatic ring allows for a limited degree of flexibility while still affording the potential to form open structures [17, 19].

The use of a combination of anionic and neutral linkers is a well-established strategy for forming high dimensional CPs with novel topologies, and most of the CPs constructed using phenylenediacetates have been obtained by employing this approach [20-22]. We have been interested in combining semi-rigid phenylenediacetates together with semi-rigid neutral linkers, as introducing a limited degree of flexibility in both the anionic and neutral linkers maximises the potential for forming novel structures. In this paper we explore the coordination polymers formed by combining zinc(II) or cadmium(II) centres together with a phenylenediacetate and 1,4-bis(2-methylbenzimidazol-1-ylmethyl) (pbmeix) linkers. Like the phenylenediacetates, pbmeix combines the possibility of facile rotation around the -CH₂- groups with the rigidity of aromatic rings providing a limited degree of flexibility, while also affording the potential for $\pi \cdots \pi$ interactions and hydrogen bonding [19, 23-25]. Herein we report the synthesis, X-ray crystal structures and properties of five new coordination polymers – [Zn(μ -opda)(μ -pbmeix)_{0.5}]_n **1** (opda = 1,2-phenylenediacetate), {[Zn(μ -ppda)(μ -pbmeix)]·H₂O}_n **2**, {[Zn(μ -ppda)(μ -pbmeix)]·0.5pbmeix·H₂O}_n **3** (ppda = 1,4-phenylenediacetate), {[Cd(μ -opda)(μ -pbmeix)]·0.5DMF}_n **4** and [Cd(μ -ppda)(μ -pbmeix)_{0.5}]_n **5**.

Experimental

Materials and measurements

All chemicals were commercially available and used without further purification with the exception of pbmeix which was prepared by a modification of a previously reported method for the synthesis of 1,4-bis(imidazol-1-ylmethyl)benzene [26]. IR spectra for **1**, **4** and **5** were recorded on a Bruker Tensor 27 FT-IR spectrometer using KBr pellets whereas the IR spectra for **2** and **3** were recorded on Perkin Elmer Spectrum 100 spectrometer mounted on a diamond ATR platform. Thermogravimetric analyses (TGA) for **1-4** were carried out with a Perkin Elmer

Diamond TG/DTA and Setaram Setsy Evolution 16/18 Thermal Analyzer in a static air atmosphere with a heating rate of 10 °C/min in the temperature range of 30–700 °C. Powder X-ray diffraction patterns (PXRD) for **1-5** were recorded on a Rikagu Smartlab X-ray diffractometer or a Bruker AXS D8 Advance diffractometer. The photoluminescence (excitation and emission) spectra for the solid state samples were determined with a Perkin-Elmer LS-55 fluorescence spectrometer. Single crystal X-ray diffraction data for **1**, **4** and **5** were collected on a Bruker APEX-II diffractometer equipped with graphite-monochromated Mo-K α radiation whereas that for **2** was collected on an Agilent SuperNova diffractometer using Cu-K α radiation that for **3** was collected on an Agilent XCalibur diffractometer using Mo-K α radiation.

The structures were solved by direct methods using the programs OLEX2 [27] and SHELXT-2015 [28] with anisotropic thermal parameters for all non-hydrogen atoms. All non-hydrogen atoms were refined anisotropically by full-matrix least-squares methods using SHELXL-2015 [29], and structural figures were obtained using MERCURY [30]. Topological analysis was performed using ToposPro [31]. Crystal data and structure refinement parameters for the complexes are presented in Table 1. Selected bond lengths and angles are listed in Tables S1-S5. The crystallographic information files of **1-5** can be obtained from the Cambridge Crystallographic Data Centre (CCDC) and the compounds have the deposition numbers CCDC 1853013-1853017, respectively [32].

Synthesis

Synthesis of [Zn(μ -opda)(μ -pbmeix)_{0.5}]_n (1**).** A mixture of H₂opda (0.15 g, 0.8 mmol), Zn(O₂CMe)₂·2H₂O (0.17 g, 0.8 mmol) and pbmeix (0.21 g, 0.8 mmol) was dissolved in DMF/H₂O (32 mL, v:v = 1:3) in a 45 mL Parr brand teflon-lined acid digestion bomb. This was sealed and then heated at 120 °C for 7 days, before cooling at a rate of 5 °C h⁻¹ to room temperature. Colourless crystals of **1** were collected by filtration and washed with water. FTIR

(KBr, cm^{-1}): 3128 w, 3059 w, 3026 w, 2960 w, 2914 w, 1631 s, 1552 vs, 1440 s, 1411 s, 1367 s, 1271 m, 1153 w, 723 m.

Synthesis of $\{[\text{Zn}(\mu\text{-ppda})(\mu\text{-pbmeix})]\cdot\text{H}_2\text{O}\}_n$ (2). A mixture of H_2ppda (0.10 g, 0.5 mmol), $\text{Zn}(\text{O}_2\text{CMe})_2\cdot 2\text{H}_2\text{O}$ (0.11 g, 0.5 mmol) and pbmeix (0.14 g, 0.5 mmol) was dissolved in DMF/ H_2O (12 mL, v:v = 1:3) in a thick walled glass tube. This was sealed and then heated at 120 °C for 3 days, before cooling at a rate of 5 °C h^{-1} to room temperature. The solution was filtered and left for slow evaporation. After a few days, colourless crystals of **2** were collected by filtration and washed with water. FTIR (KBr, cm^{-1}): 3510 w, 3130 w, 3000 w, 2963 w, 2914 w, 1606 s, 1602 s, 1516 vs, 1440 s, 1422 s, 1364 s, 1277 m, 1144 w, 740 m.

This reaction was found to be very sensitive to conditions, and on some occasions $\{[\text{Zn}(\mu\text{-ppda})(\mu\text{-pbmeix})]\cdot 0.5\text{pbmeix}\cdot\text{H}_2\text{O}\}_n$ **3** was formed instead of **2**. FTIR (KBr, cm^{-1}): 3424 w, 3151 w, 3132 w, 2915 w, 1638 vs, 1536 w, 1521 w, 1518 s, 1432 s, 1403 s, 1309 m, 1284 m, 1150 w, 1012 m, 712 m.

Synthesis of $\{[\text{Cd}(\mu\text{-opda})(\mu\text{-pbmeix})]\cdot 0.5\text{DMF}\}_n$ (4). A mixture of H_2opda (0.10 g, 0.5 mmol), $\text{CdCl}_2\cdot 2\text{H}_2\text{O}$ (0.090 g, 0.5 mmol) and pbmeix (0.27 g, 1 mmol) was dissolved in DMF (18 mL) was placed in a 45 mL Parr brand teflon-lined acid digestion bomb. This was sealed and then heated at 120 °C for 5 days, before cooling at a rate of 5 °C h^{-1} to room temperature. Colourless crystals of **4** were collected by filtration and washed with water. FTIR (KBr, cm^{-1}): 3114 m, 3024 w, 2927 w, 1679 s, 1587 s, 1556 vs, 1504 m, 1382 m, 1280 w, 1002 w, 775 m.

Synthesis of $\{[\text{Cd}(\text{ppda})(\text{pbmeix})_{0.5}]\}_n$ (5). A mixture of H_2ppda (0.15 g, 0.8 mmol), $\text{Cd}(\text{O}_2\text{CMe})_2\cdot 2\text{H}_2\text{O}$ (0.21 g, 0.8 mmol) and pbmeix (0.20 g, 0.8 mmol) was dissolved in DMF/ H_2O (32 mL, v:v = 1:3) and was placed in a 45 mL Parr brand teflon-lined acid digestion bomb. This was sealed and then heated at 120 °C for 5 days, before cooling at a rate of 5 °C h^{-1}

to room temperature. Colourless crystals of **5** were collected by filtration and washed with water. FTIR (KBr, cm^{-1}): 3126 w, 3024 w, 2943 m, 1558 vs, 1510 s, 1421 s, 1388 vs, 1282 m, 1149 w, 734 m.

Results and Discussion

Syntheses

The compounds $[\text{Zn}(\mu\text{-opda})(\mu\text{-pbmeix})_{0.5}]_n$ **1**, $\{[\text{Zn}(\mu\text{-ppda})(\mu\text{-pbmeix})]\cdot\text{H}_2\text{O}\}_n$ **2** and $\{[\text{Zn}(\mu\text{-ppda})(\mu\text{-pbmeix})]\cdot 0.5(\text{pbmeix})\cdot\text{H}_2\text{O}\}_n$ **3** were prepared as single crystals through the reactions between zinc(II) acetate, 1,2- or 1,4-phenylenediacetic acid ($\text{H}_2\text{opda}/\text{H}_2\text{ppda}$) and 1,4-bis(2-methylimidazol-1-ylmethyl)benzene (pbmeix) in DMF/water on heating at 120°C for 3-7 days. For the analogous cadmium systems, the reaction between cadmium(II) acetate, H_2ppda and pbmeix gave $[\text{Cd}(\mu\text{-ppda})(\mu\text{-pbmeix})_{0.5}]_n$ **5** under similar conditions after 5 days, but the reaction with H_2opda gave only a non-crystalline precipitate under these conditions. However, on changing the cadmium source to cadmium(II) chloride and the solvent to DMF, single crystals of $\{[\text{Cd}(\mu\text{-opda})(\mu\text{-pbmeix})]\cdot 0.5\text{DMF}\}_n$ **4** were formed after 5 days at 120°C . The PXRD patterns for compounds **1-4** (Fig. S1-S4) were found to match well with those simulated from their single crystal X-ray structures, indicating the phase purities of the complexes. However, PXRD patterns of the bulk material of compound **5** indicate that the material is not phase pure (Fig. S5), with the compound identified crystallographically being present as a minor component in the bulk material. The reaction was repeated using a variety of different conditions, but in all cases the product contained a mixture of phases.

X-Ray crystallographic analysis

$[\text{Zn}(\mu\text{-opda})(\mu\text{-pbmeix})_{0.5}]_n$ (**1**). Compound **1** was formed from reaction of zinc(II) acetate with H_2opda and pbmeix in DMF/water at 120°C . The compound crystallises in the monoclinic space group $P2_1/c$ and the asymmetric unit contains one zinc(II) centre, one opda ligand and half a

pbmeix ligand (Fig. 1). The zinc centre is four-coordinate, bonding to three oxygen atoms from three different opda ligands and one nitrogen atom from the pbmeix ligand. It exhibits distorted tetrahedral geometry ($\tau_4 = 0.81$) [33], with the bond angles ranging from $98.08(12)$ to $127.32(18)^\circ$. The Zn(1)–O bond distances are in the range of $1.916(3)$ – $2.018(2)$ Å, whereas the Zn(1)–N(1) bond length is $1.990(3)$ Å. The carboxylate group containing O(1) and O(2) bridges between zinc centres, leading to the formation of chains along the crystallographic *c* axis. These chains are connected into sheets by the opda linkers. Overall, the opda linkers adopt a $\mu_3\text{-}\eta^1\text{:}\eta^1\text{:}\eta^1\text{:}\eta^0$ coordination mode through linking the zinc centres, and the opda ligands adopt a trans conformation, constructing sheets in the *bc* plane (Fig. 2). The Zn(1)⋯Zn(1)^{*i*} and Zn(1)⋯Zn(1)^{*ii*} distances are 4.721 and 7.199 Å, respectively ((*i*) $x, \frac{1}{2} - y, -\frac{1}{2} + z$, (*ii*) $1 - x, \frac{1}{2} + y, \frac{1}{2} - z$). The distance between the zinc(II) centres bridged by the pbmeix linker is 14.303 Å. The torsion angles between the carboxylate groups and their adjacent aromatic rings are -98.64° (through C1–C2–C3–C4) and -103.02° (through C10–C9–C8–C7). Adjacent sheets are inter-linked by pbmeix ligands to generate a 3D framework (Fig. 3a). Topologic analysis reveals that complex **1** has xww-3,4-*P2*₁/*c* topology with the point symbol of $(4.8^2.10^3)(4.8^2)$ (Fig. 3b).

$\{[\text{Zn}(\mu\text{-ppda})(\mu\text{-pbmeix})]\cdot\text{H}_2\text{O}\}_n$ (2**).** Compound **2** was formed following the reaction of zinc(II) acetate with H₂ppda and pbmeix in DMF/water at 120°C. It crystallises in the triclinic space group *P*-1, and the asymmetric unit contains one zinc(II) centre, two half ppda ligands, one pbmeix ligand and one included water molecule. As shown in Fig. 4, the Zn(II) centre is coordinated by two oxygen atoms of the carboxylate groups from two different ppda ligands and two nitrogen atoms from two different pbmeix ligands. Overall it exhibits distorted tetrahedral geometry ($\tau_4 = 0.92$) [33], with bond angles ranging from 102.88(12) to 115.69(12)°. The Zn(1)–O(1) and Zn(1)–O(3) bond distances are 1.938(3) and 1.945(2) Å, whereas the Zn(1)–N(1) and Zn(1)–N(4) bond lengths are 1.993(4) and 2.048 (4) Å, respectively. In contrast to **1**, there are no bridging carboxylate groups in **2**. The ppda coordinates to the metal centre through the $\mu_2\text{-}\eta^1:\eta^0:\eta^1:\eta^0$ coordination mode, and the CH₂CO₂ groups are twisted with respect to each other indicating a typical trans conformation. Each ppda ligand connects two zinc(II) centres to form an infinite one-dimensional zig-zag polymeric chain, and the adjacent chains are further linked together by two different pbmeix ligands to form a 2D network along the *ab* plane (Fig. 5a and 5b). These sheets contain large hexagonal rings (distance across 17.8 Å) with four sides constructed from ppda ligands and two sides made from pairs of pbmeix ligands, that themselves form Zn₂(pbmeix)₂ rings. The Zn(1)⋯Zn(1)^{*i*} and Zn(1)⋯Zn(1)^{*ii*} distances are 12.565 and 13.743 Å, respectively ((*i*) $-x, 1 - y, 2 - z$, (*ii*) $2 - x, 2 - y, 1 - z$). The distance between the zinc(II) centres bridged by the pbmeix linkers is 11.667 Å. These 2D layers are interpenetrated to give a 2D + 2D → 2D parallel interpenetrated structure (Fig. 6a). The interpenetration occurs when ppda ligands from one network penetrate the Zn₂(pbmeix)₂ rings of a neighbouring network, generating a polycatenane structure. Topologically, complex **2** is a 2-fold parallel interpenetrated 3-nodal (2,2,4)-connected 2D + 2D → 2D framework with the point symbol of (12)(4.12⁵)(4) (Fig. 6b).

$\{[\text{Zn}(\mu\text{-ppda})(\mu\text{-pbmeix})]\cdot 0.5\text{pbmeix}\cdot \text{H}_2\text{O}\}_n$ (3). Like **2**, compound **3** was formed from the reaction of zinc(II) acetate, pbmeix and H₂ppda in DMF/water at 120°C. It crystallises in the triclinic space group *P*–1 and the asymmetric unit (Fig. 7) contains one Zn(II) centre, one ppda ligand, one pbmeix ligand, half an uncoordinated pbmeix molecule and one included water molecule. The Zn(II) ion is coordinated to two nitrogen atoms (N1 and N4ⁱⁱ) from two different pbmeix ligands and two carboxylate oxygen atoms (O1 and O3ⁱ) from two different ppda ligands [(*i*) *x* + 1, *y*, *z*; (*ii*) *–x* + 2, *–y* + 1, *–z*]. Overall, it exhibits a distorted tetrahedral coordination geometry ($\tau_4 = 0.78$) [33], with the bond angles ranging from 95.76(8) to 133.49(9)°. The Zn–N bond distances are 2.024(2) and 2.020(2) Å and the Zn–O bond distances are 1.9340(19) and 1.9316(19) Å. The ppda coordinates to the Zn(II) centre through the $\mu_2\text{-}\eta^1\text{:}\eta^0\text{:}\eta^1\text{:}\eta^0$ coordination mode, and the CH₂CO₂ groups of ppda linker are twisted with respect to each other, in a trans conformation. The Zn(II) centres are connected by ppda ligands to form 1D chains (Fig. 8a), and these are inter-linked by pbmeix ligands to generate a 1D nanotubular structure (Fig. 8b) in which pairs of pbmeix ligands bridge two Zn(II) ions to form Zn₂(pbmeix)₂ 26-membered rings. The included, uncoordinated pbmeix reside within these nanotubes, with each Zn₂(pbmeix)₂ ring being penetrated by a pbmeix molecule (Fig. 8c). This contrasts with the structure of **2**, as in that case the Zn₂(pbmeix)₂ rings were penetrated by ppda linkers. It is notable that the imidazolyl rings from neighbouring pbmeix molecules lie parallel to each other, and the short distance between them (3.547 Å) is consistent with $\pi\cdots\pi$ interactions. Metal-organic nanotubular structures have previously been shown to possess interesting properties and have potential applications in gas and solvent adsorption, and sensing small molecules [34–36]. Neighbouring 1D nanotubular structures and the included pbmeix and H₂O are connected through hydrogen bonding, C–H $\cdots\pi$ and $\pi\cdots\pi$ interactions to construct a 3D supramolecular network. Topologically, complex **3** is uninodal (3)-connected 1D nanotubular structure and displays SP 1-periodic net topology with the point symbol of (4².6) (Fig. S6).

Fig. 7. Part of the structure of **3** with the atom numbering scheme showing the asymmetric unit.

Fig. 8. The structure of **3** showing (a) a 1D polymeric chain, (b) inter-linking of the chains to form nanotubes and (c) a view down the axis of a nanotube. Hydrogen atoms have been omitted for clarity.

$\{[\text{Cd}(\mu\text{-opda})(\mu\text{-pbmeix})]\cdot 0.5\text{DMF}\}_n$ (4). Compound **4** was formed from the reaction of cadmium(II) chloride with H₂opda and pbmeix in DMF at 120 °C. The topology of the structure of **4** is similar to that of **3**, despite the difference in the metal centre and phenylenediacetate. An X-ray structural analysis demonstrates that **4** crystallises in the monoclinic space group $P2_1/c$. The asymmetric unit contains one cadmium(II) centre, one opda ligand, one pbmeix ligand and half an included DMF molecule. As shown in Fig. 9, the cadmium(II) centre is six coordinate, bonding to the four oxygen atoms of two carboxylate groups, both from a different opda ligand, and two nitrogen atoms from two pbmeix ligands, thus exhibiting distorted octahedral geometry. The two carboxylate groups are unsymmetrically coordinated, with that involving O(1) and O(2) being closer to being monodentate (Cd(1)–O(1) 2.233(3), Cd(1)–O(2) 2.752(4) Å) than that involving Cd(3) and Cd(4) (Cd(1)–O(3) 2.332(3), Cd(1)–O(4) 2.408(3) Å). The opda ligand coordinates to the metal centre through the $\mu\text{-}\eta^1\text{:}\eta^1\text{:}\eta^1\text{:}\eta^1$ coordination mode, and the CH₂CO₂ groups are twisted with respect to each other, indicating a trans conformation. The cadmium(II) centres are connected by opda ligands to form a 1D chain (Fig. 10a) with a Cd(1)⋯Cd(1)^{*i*} distance of 8.695 Å ((*i*) –1 + *x*, *y*, *z*). These 1D chains are connected by pbmeix ligands to generate a 1D nanotubular structure (Fig. 10b,c) that contains Cd₂(pbmeix)₂ 26-membered rings. Although topologically nanotubular, in practice the close approach of the pbmeix ligands pinch the nanotubes and lead to the formation of discrete pores of approximate window dimensions 6.2 × 2.9 Å, and the included DMF molecules reside in these positions. The nanotubes are linked into the gross 3D supramolecular structure by a combination of C–H⋯π and π⋯π interactions. Topologically, complex **4** forms a uninodal (3)-connected 1D nanotubular structure and displays SP 1-periodic net topology with the point symbol of (4².6) (Fig. S7).

Fig. 9. Part of the structure of **4** with the atom numbering scheme showing the asymmetric unit.

Fig. 10. The structure of **4** showing (a) the 1D polymeric Cd(opda) chains (b) the overall nanotubular structure, and (c) a view down the nanotube. Hydrogen atoms have been omitted for clarity.

[Cd(μ -ppda)(μ -pbmeix)_{0.5}]_n (5). Compound **5** was formed from the reaction of cadmium(II) acetate with H₂ppda and pbmeix in DMF/water at 120°C. Single-crystal X-ray diffraction analysis reveals that **5** crystallises in the monoclinic space group *C2/c*. As shown in Fig. 11, the asymmetric unit of complex **5** contains one cadmium(II) centre, half a pbmeix ligand and one ppda ligand. Each cadmium(II) centre is seven-coordinate, bonding to six carboxylate oxygen atoms from four different ppda ligands and one nitrogen atom from a pbmeix ligand, and overall exhibits distorted pentagonal bipyramidal geometry. The cadmium centres are bridged by carboxylate groups into one-dimensional chains, with each carboxylate acting as a bidentate ligand to one cadmium centre, and one of the carboxylate oxygen atoms coordinates to a neighbouring cadmium centre. Each of the carboxylate groups coordinates in a bidentate manner to one cadmium centre as well as bridging through one of the oxygen atoms to another cadmium centre. The bidentate modes are both unsymmetrical (Cd(1)–O(1) 2.280(2), Cd(1)–O(2) 2.652(3), Cd(1)–O(3) 2.336(3), Cd(1)–O(4) 2.664(3) Å), with the longer bond formed by the oxygen atom bridging to the second metal centre (Cd(1)ⁱ–O(2) 2.481(3), Cd(1)ⁱ–O(4) 2.355(3) Å). The ppda ligands coordinate to the metal centre through the μ_4 - η^2 : η^1 : η^2 : η^1 coordination mode and serve to link the chains into a three-dimensional (3D) framework (Fig. 12a). The CH₂CO₂ groups of ppda linker are twisted with respect to each other, in a trans conformation. This structure is further stabilised by coordination of the pbmeix ligand (Fig. 12b). Topologic results show that complex **5** is a 2-nodal (4,5)-connected 3D framework with the point symbol of (4³.6².7)(4³.6⁴.7².8)(4) (Fig. 13).

Discussion

Comparing the metal centres in the coordination polymers **1-5** it can readily be seen that there is a tendency to increase the coordination numbers with the size at the metal centre. In **1-3**, the zinc(II) centre is four-coordinate in a distorted tetrahedral environment whereas, in contrast, in **4** and **5**, the coordination number of the larger cadmium(II) centre is six and seven, respectively. This is reflected in the carboxylate coordination modes, with the carboxylates in **1**, **2** and **3**, coordinating to the zinc(II) centres through single oxygen atoms, whereas those in **4** and **5** coordinate in a bidentate manner to the cadmium(II) centres.

With respect to the phenylenediacetate ligands, all of the carboxylic acid groups of the H₂opda and H₂ppda reagents are deprotonated in the products. The products show four different coordination modes (Fig. 14), indicating the versatility of these linkers. For both opda and ppda, the change in metal centre leads to a change in dimensionality at the product though not in a consistent way. Thus, the Zn-opda compound **1** forms a 3D network whereas the analogous Cd-opda compound **4** forms lower dimensional 1D nanotubes. In contrast, Zn-ppda compounds **2** and **3** form a 2D network and 1D nanotubes, respectively whereas the analogous Cd-ppda compound **5** forms a higher dimensional 3D network.

Fig. 14. The coordination modes of the o/ppda ligands in **1-5**.

It is notable that compounds **1** and **5** include only half an equivalent of pbmeix per metal centre, whereas **2** and **4** contain one equivalent of pbmeix per metal. In all cases one (or more) equivalents of pbmeix per metal ion were used in the reaction mixture and changing the ratio of reactants does not afford other phases. In addition to coordinated pbmeix, compound **3** contains half an equivalent of included, uncoordinated pbmeix.

Zinc(II) ppda complexes with other semi-rigid *N,N'*-donor co-linkers have been reported previously and shown to form one- [7, 37] two- [7, 15, 38, 39] and three-dimensional [40-42] networks. Although some of the 3D networks are interpenetrated, none of the previously reported zinc ppda compounds form a polycatenane structure similar to that adopted by **2**. The network displayed by $\{[\text{Zn}(\mu\text{-ppda})(\mu\text{-mbix})]\cdot 0.5\text{H}_2\text{O}\}_n$ (mbix=1,3-bis(imidazol-1-ylmethyl)benzene) [7], contains similar sheets to those in **2**, though without the interpenetration. In contrast, the 1D chains of $[\text{ZnCl}(\mu\text{-ppda})_{0.5}(\mu\text{-mbtx})]_n$ (mbtx = 1,1'-(1,3-phenylenebis(methylene))bis(1*H*-1,2,4-triazole)) contain a similar type of catenation to that seen in **2**, despite the difference in framework dimensionality [37]. While there are previous examples of cadmium(II)-opda networks containing semi-rigid *N,N'*-donor co-ligands, none have similar nanotubular structures to that adopted by **4**. It is therefore clear that when using semi-rigid ligands, small changes in the ligand can have dramatic structural consequences.

Thermal Properties and Photoluminescence Behaviour

In order to explore the thermal stabilities of the complexes, thermogravimetric analyses were undertaken on **1-4** under an air atmosphere in the temperature range 30-700 °C (Fig. S8). For compounds **2** and **3**, the first mass losses in the temperature range 74-192 °C and 63-223 °C were related to removal of the included water molecules (found: 3.16 %, calcd.: 3.32 % for **2** and found: 3.04 %, calcd.: 2.92 % for **3**), respectively. Complexes **1** and **4** were stable up to 268 and 194 °C, respectively. For compound **4**, the weight loss of 10.47 % in the temperature range 194-285°C was due to removal of one DMF molecule (calcd.: 11.33 %). On further heating, all

complexes were fully decomposed, with the residues the oxides (ZnO, found: 19.93 %, calcd: 20.73 % for **1**; ZnO, found: 16.66 %, calcd: 14.95 % for **2**; ZnO, found: 14.96 %, calcd: 13.15 % for **3**, CdO, found: 21.13 %, calcd: 19.94 % for **4**).

The photoluminescent properties of H₂opda as well as its complexes **1** and **4** at room temperature were determined. Emissions were observed at 370 and 389 nm ($\lambda_{\text{ex}} = 292$ nm) for H₂opda, which were attributed to $\pi^* \rightarrow \pi$ transitions. Intense broad emission peaks appeared at 389 nm ($\lambda_{\text{ex}} = 315$ nm) for **1** and 435 nm ($\lambda_{\text{ex}} = 315$ nm) for **4**. The emissions of the complexes were neither ligand-to-metal charge transfer nor metal-to-ligand charge transfer, as oxidation or reduction of d¹⁰ metal centres is difficult. The emissions of the complexes are likely due intra-ligand transitions of the phenylenediacetate ligands though that for **4** is at a higher wavelength than for H₂opda (Fig. S9).

Conclusions

Five coordination polymers containing a 1,4-bis(2-methylimidazol-1-ylmethyl)benzene (pbmeix) and a phenylenediacetate (opda or ppda) ligand have been prepared and structurally characterised. Both the nature of the metal centre and the identity of the phenylenediacetate influence the dimensionality of the products formed, with one-, two- and three-dimensional networks all identified crystallographically. In complexes **1-3**, some of the oxygen atoms of o/ppda take part in coordination with zinc(II) whereas in complexes **4** and **5**, all the oxygen atoms of o/ppda coordinate to cadmium(II). Both the coordination environment of the metal ions and the bonding mode of o/ppda linkers in these coordination polymers show differences. The opda ligands in complexes **1** and **4** adopt the $\mu_3\text{-}\eta^1\text{:}\eta^1\text{:}\eta^1\text{:}\eta^0$ tridentate and $\mu_2\text{-}\eta^1\text{:}\eta^1\text{:}\eta^1\text{:}\eta^1$ tetradentate coordination modes whereas the ppda ligands in complexes **2**, **3** and **5** show the $\mu_2\text{-}\eta^1\text{:}\eta^0\text{:}\eta^1\text{:}\eta^0$ bidentate and $\mu_4\text{-}\eta^2\text{:}\eta^1\text{:}\eta^2\text{:}\eta^1$ hexadentate coordination modes, respectively. The comparison of the structures of these compounds and those with other semi-flexible ligands show that the dimensionality of **1-5** can be adjusted by adding methyl group to the neutral linker.

The various bonding modes and ligand conformations of opda/ppda, the methyl group of the linker pbmeix and the nature of the metal centre all play important roles in determining the structural diversity.
